

**ABSTRACT OF THE DISCLOSURE**

5       An improved pallet made of a synthetic resin wherein the underside  
of the upper deck is substantially planar, and the supports which separate the upper  
and lower decks are integrally formed with and project upwardly from the lower  
deck, and are secured to the underside of the upper deck. The upper ends of the  
supports are received in recesses in the underside of the upper deck, and the recesses  
and the supports preferably have mating elements which snap-actingly engage one  
10 another to lock the supports in the recesses when the decks are assembled.  
Preferably, the supports are tapered, the lower ends of the supports being wider than  
the upper ends thereof. Top surface of the upper deck, the bottom surface of the  
lower deck, and the underside of the upper deck in the fork-receiving regions  
between the supports may have a slip-resistant scuffed texture.
